

From what I've read there are 3 main cloud services that are popular.

GCP or Google Cloud Platform, AWS or Amazon Web Services and Microsoft Azure.

Even though all of them are cloud services each one of them has a different advantage.

Let's take a look at Microsoft Azure, it has one of the biggest advantages if you're already using Microsoft stack, it natively connects to other Microsoft services like, Active Directory, Windows, SQL servers and Power BI to turn data outputs into dashboards.

For our second option, let's look at AWS or Amazon Web Services,

This option has the largest market share out of all of the options, meaning that in most cases, employers will ask for experience in AWS.

It also has Amazon S3 which is widely used in the tech industry for reliable and scalable data lakes.

Our third option that I choose to include here is GCP, or Google Cloud Platform. This option is the best for AI and ML, providing major advantages in the ML tools that it provides, connects with Google's AI technologies like Gemini and TensorFlow.

Also it provides BigQuery that allows you to analyze large amount of data in seconds by just using SQL.

There are more cloud services which I've not included in this article, for which has their own advantages. but these are the three of the most popular cloud services available currently (7th June, 2026).

Microsoft Azure, AWS and GCP, all of them have advantages and what we will choose to use will be based on the tasks we have to complete or what the company we're in uses, but all three of them are great options for data science.
